
♦ WHAT IS Gmail MADE OF?

When you open Gmail:

Subject: Hello

**Hi bro,
How are you?**

You see text.

But the browser does NOT see text.

The browser sees HTML elements.

Something like:

```
<div>
  Subject: Hello
</div>

<div class="a3s ail">
  Hi bro,
  How are you?
</div>
```

♦ WHAT IS a3s ?

a3s

is NOT JavaScript.

It is NOT a variable.

It is NOT a function.

It is NOT a keyword.

It is simply a Gmail CSS class name.

Example:

```
<div class="a3s">
```

Here:

a3s

is just a name chosen by Gmail developers.

Like:

```
Tanbir
```

is a name.

Gmail could have named it:

```
emailBody
```

or

```
abc123
```

But they chose:

```
a3s
```

♦ WHAT IS aiL ?

Same thing.

Example:

```
<div class="a3s aiL">
```

This element has TWO class names:

```
a3s
```

and

```
aiL
```

Think:

```
class="red big"
```

has:

```
red  
big
```

Two class names.

Similarly:

```
class="a3s aiL"
```

has:

```
a3s
aiL
```

♦ WHY DO WE NEED THEM?

Because your extension must find the email text.

Suppose Gmail page contains:

```
Header
Menu
Settings
Email Content
Footer
```

How does the extension know where the **email content** is?

It searches using class names.

♦ WHAT DOES THIS MEAN?

```
document.querySelector(".a3s.aiL")
```

Think:

```
Find me the HTML element
whose class is

a3s
and
aiL
```

That's all.

♦ REAL WORLD EXAMPLE

Suppose classroom:

```
Student A
Student B
Student C
Student D
```

Now I say:

```
Find student wearing
Red Shirt
and
Black Cap
```

You look around.

When found:

Student C

you point to him.

That's exactly what:

```
querySelector()
```

does.

- ♦ WHAT DOES querySelector RETURN?

Suppose Gmail contains:

```
<div class="a3s ail">
  Congratulations!
  You won $1000
</div>
```

Then:

```
document.querySelector(".a3s.ail")
```

finds that element.

Result:

```
emailBody
↓
<div class="a3s ail">
  Congratulations!
  You won $1000
</div>
```

- ♦ WHY STORE IT IN emailBody?

Because later we need the text inside it.

Think:

```
emailBody
```

is like a remote control pointing to that Gmail email box.

It does NOT contain text yet.

It only knows:

```
Where the email is located
```

- ♦ THEN WHAT DOES innerText DO?

Suppose:

```
emailBody
↓
<div class="a3s ail">
  Congratulations!
  You won $1000
</div>
```

Now:

```
emailBody.innerText
```

means:

```
Give me the text
inside that element
```

Result:

```
Congratulations!
You won $1000
```

◆ THEN WHAT DOES return DO?

```
return emailBody.innerText
```

means:

```
Send the email text
back to whoever called this function
```

Result:

```
"Congratulations! You won $1000"
```

◆ COMPLETE FLOW

```
Gmail Page
↓
<div class="a3s ail">
  Congratulations!
  You won $1000
</div>

↓
querySelector(".a3s.ail")

↓
Find that email box

↓
Store it in emailBody

↓
emailBody.innerText

↓
"Congratulations! You won $1000"
```

```
function getEmailText() {
  let emailBody =
    document.querySelector(".a3s.ail") ||
    document.querySelector(".a3s");

  return emailBody ? emailBody.innerText : "";
}
```

```
↓  
return  
  
↓  
getEmailText() returns the email text
```

The biggest thing to remember:

```
a3s and aiL are not JavaScript.  
They are Gmail's HTML class names.  
querySelector() uses those names to locate the email body on the page.
```

Once this clicks, the whole function becomes much easier to understand. 👍
