

no java before code

No problem bro. Let's forget the complicated explanation and start from the beginning.

You have:

```
fetch("http://localhost:8080/email/analyze", {
  method: "POST",
  headers: {
    "Content-Type": "application/json"
  },
  body: JSON.stringify({
    emailText: text
  })
})
```

♦ WHAT IS FETCH?

Think:

```
fetch()
```

means:

```
Send a request to a server
```

Example:

```
fetch("http://localhost:8080/email/analyze")
```

means:

```
Hey Spring Boot,
I'm contacting you.
```

♦ WHY IS THERE A COMMA?

Notice:

```
fetch(
  "http://localhost:8080/email/analyze",
  { ... }
)
```

There are TWO things being passed.

First:

```
"http://localhost:8080/email/analyze"
```

→ where to send request

Second:

```
{ ... }
```

→ extra instructions

♦ WHAT IS THIS?

```
{
  method: "POST",
  headers: {...},
  body: ...
}
```

This is called the options object.

You can think:

options

means:

Instructions for fetch

Real-life example:

Suppose you send a courier.

You tell courier:

Address:
Pune

That's like:

"http://localhost:8080/email/analyze"

Then you give extra instructions:

Urgent delivery
Fragile package
Contains documents

Those are like:

method
headers
body

They are settings for the request.

♦ WHAT IS method?

method: "POST"

means:

```
I am sending data  
to the server
```

Without POST:

```
Spring won't receive  
your email text
```

♦ WHAT IS body?

Think:

```
body
```

means:

```
The actual data  
I want to send
```

Example:

If I send a letter:

```
Envelope  
↓  
Letter inside
```

The letter inside is the body.

Your project:

```
body: ...
```

contains:

```
email text
```

that Gmail extracted.

Suppose:

```
text =  
"Free money now"
```

Then:

```
body
```

contains:

Free money now

which gets sent to Spring Boot.

♦ WHAT IS JSON.stringify()?

Suppose you create:

```
{
  emailText: text
}
```

If:

```
text = "Hello"
```

then:

```
{
  emailText: "Hello"
}
```

This is a JavaScript object.

But HTTP requests usually send JSON text.

So JavaScript converts:

```
{
  emailText: "Hello"
}
```

into:

```
{"emailText":"Hello"}
```

using:

```
JSON.stringify()
```

Think:

```
JavaScript Object
↓
JSON.stringify()
↓
JSON text
↓
Sent to Spring Boot
```

The simplest way to remember:

```
fetch()
```

= send request

```
options
```

= settings/instructions for fetch

```
method: "POST"
```

= I'm sending data

```
body
```

= the data being sent

```
JSON.stringify()
```

= convert JavaScript object into JSON text before sending

Before we go to `.then(res => res.json())`, tell me:

Do you understand why **body** is needed at all? In your spam detector project, what data is being placed inside the body?
